- Ventilation plays a key role for a safe operation of a tunnel.
- Clear guidelines for design and operation of ventilation systems are given in various international publications, like PIARC, but also on national level.
- Very often, however, special boundary conditions given by geological conditions in mountainous areas or existing buildings and other structural constraints in built-up areas force special solutions for ventilation systems that deviate significantly from standardized specifications.

Retrofitting of existing systems is made considerably more difficult by the fact that current safety requirements have to be applied to existing structures.

Two examples for upgrading road tunnels:

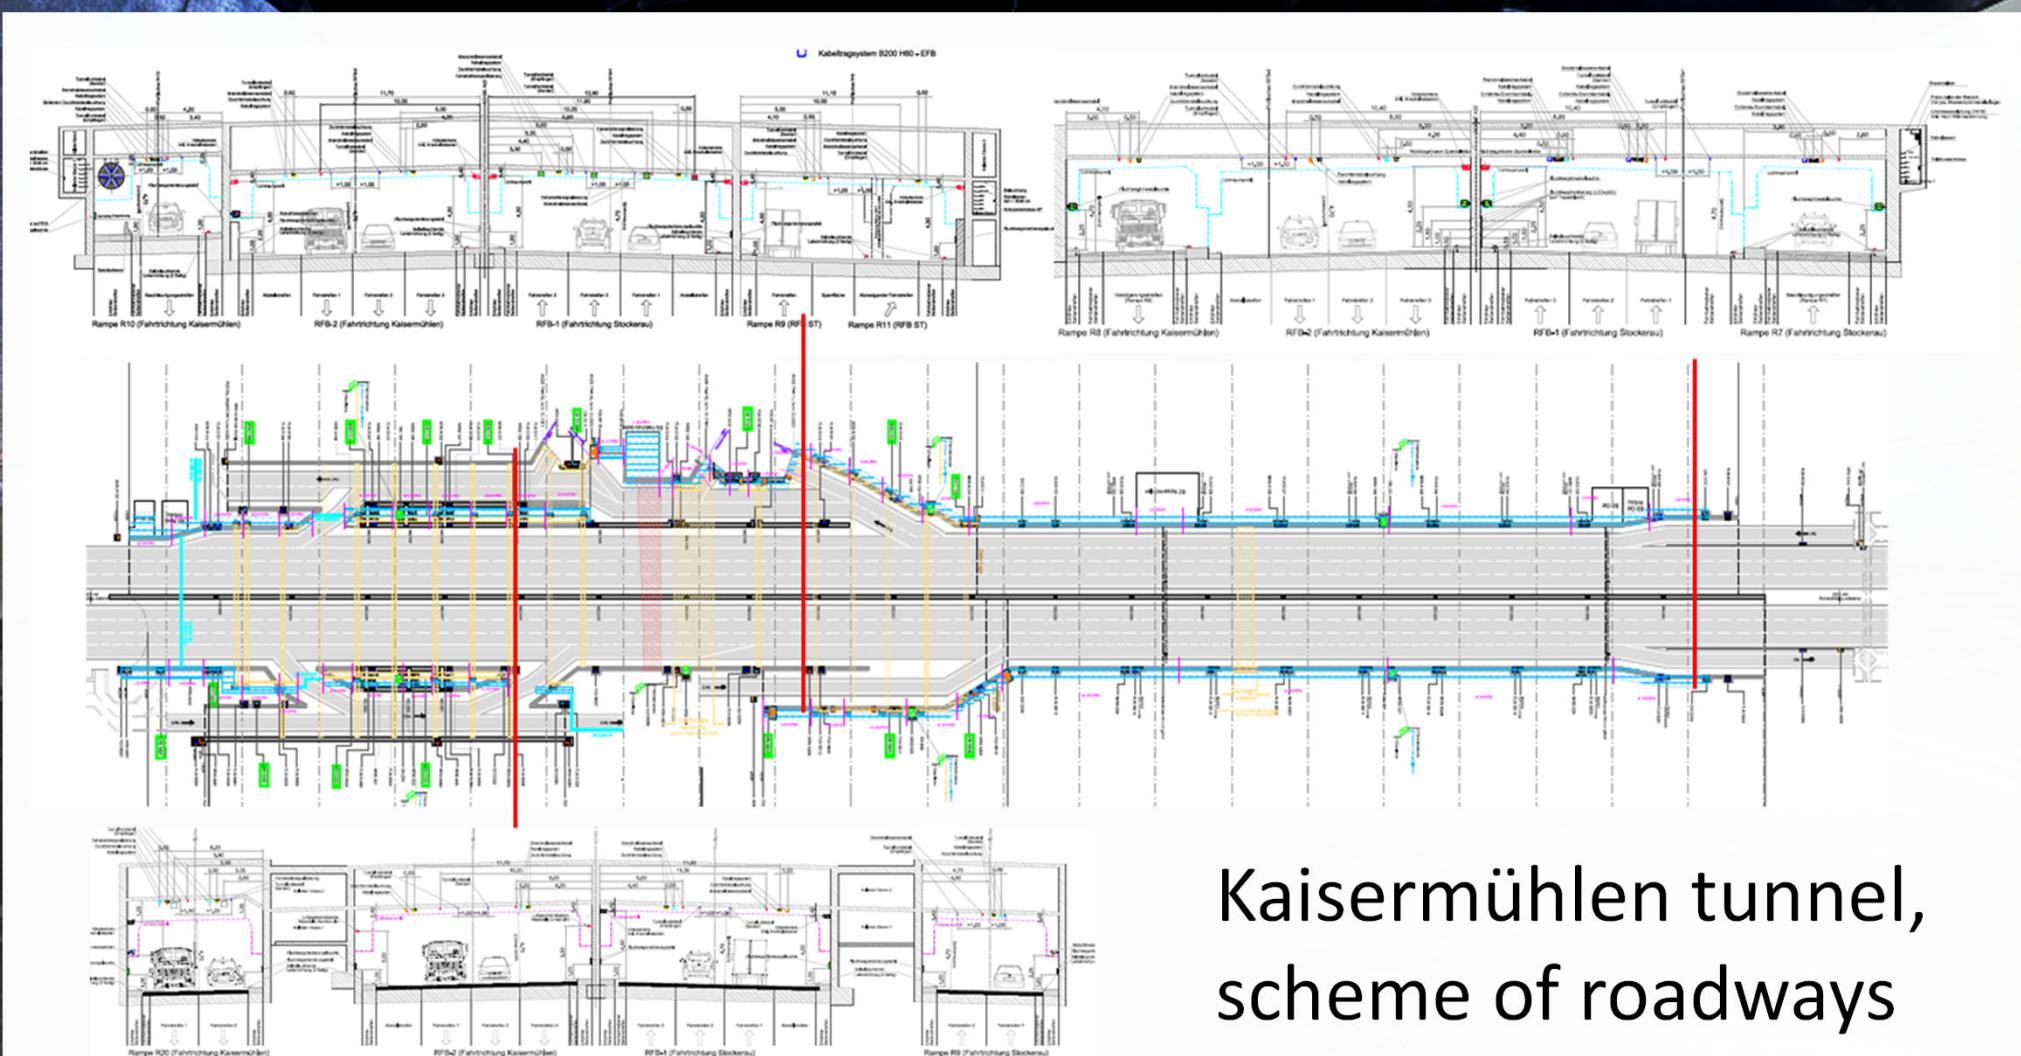

- Arlberg road tunnel (A), 15.5 km long single tube tunnel, bidirectional traffic
- Kaisermühlen tunnel, Vienna (A), 2.2 km long heavily trafficked tunnel, retrofitting under operation

Kaisermühlen tunnel, Vienna (A)

- Part of the city highway system in Vienna
- >116,000 veh/day, uni-directional traffic, congestions quite frequent
- Tunnel length 2.2 km, up to 6 lanes per tube
- 10 extra on/off ramps
- 2 connections to adjacent tunnels
- Major part of the road network within the city but also for transit
- No restrictions for dangerous goods vehicles (direct connection to important oil infrastructure in the east of Vienna)
- Refurbishment done under operation

Kaisermühlen tunnel, old design - partial air
recirculation

— *Implementación de tecnologías en la operación de túneles* —
29 de marzo al 1 de abril de 2022

- Longitudinal ventilation with jet fans
- Existing tunnel (1990), quite small space for fans, 70 small fans (300 N) per tube
- Refurbishment: erection of niches for fans + portal installations
- Jet fans: thrust 2000 N, 1.6 m outer diameter, full reversible

Fire zone W10

→ Fresh air
→ Smoke

- Complex tunnels/tunnel networks are common means for managing traffic in urban areas
- Connected aerodynamics require closed loop ventilation control [PI(D)] in fire case
- Speed controlled jet fans are necessary
- In depth on-site testing is necessary to define the parameters for the control scheme
- Testing requires time
- Complex control system needs a high quality standard of sensors and recurrent service and maintenance

Arlberg Tunnel (A)

- Length 15.5 km, single tube, bidirectional traffic
 - Traffic: ~8'000 veh/d, 17% HGV
 - Full transverse ventilation system
 - In operation since 1978
 - Egress ways to the parallel running rail tunnel ~ every 1'700 m built in ~ 2000
 - Since 2015 full upgrade for ventilation and safety systems, egress ways every 500 m
- Upgrading resulted in massive changes in the ventilation system and the safety/egress concept

Conclusions

- For standard tunnels design methods are straight forward and well defined.
- However, increased complexity and safety requirements need quite often a customized design which results in complex ventilation control strategies for fire cases.
- Intense testing of control systems is required before tunnel goes in operation.
- Recurrent system tests are required to provide a reliable and safe system.
